

BP Property

Summary:

The BP Property consists of 11 mineral claims totaling 400.17 ha.

Star of Hope Prospect

The Star of Hope prospect is located approximately 9 kilometres northwest of Olalla, near a pass between Bradshaw Creek and Cedar Creek. The property consists of historic Crown grants with past underground development.

The area is underlain by volcanic and sedimentary rocks intruded by diorite and gabbro. Mineralization is structurally controlled and occurs in shear zones and quartz veins associated with dikes.

Three mineralized zones have been identified. Zone B hosts the strongest results, including **12.89 g/t gold, 43.54 g/t silver, and 0.48% lead**, with additional high-grade samples up to **41.83 g/t gold and 281.15 g/t silver**. Drilling has confirmed mineralization at depth.

Mineralization consists of pyrite, arsenopyrite, galena, and pyrrhotite, with minor chalcopyrite noted.

The system is interpreted as a **polymetallic vein system with porphyry-related gold potential**, supported by geophysics and soil anomalies.

Allegro Showing

The Allegro showing is located approximately 9 kilometres northwest of Olalla, near the headwaters of Bradshaw Creek. It sits within a known mineralized corridor between nearby showings.

The property is underlain by volcanic and sedimentary rocks intruded by Okanagan granitic rocks, including diorite and granodiorite. Local alteration includes hornfels, silicification, and minor skarn, with porphyry dikes present.

Mineralization occurs in several styles. A silicified and pyritized zone returned **1.06 g/t gold and 12.68 g/t silver over 1 metre**. Molybdenite and powellite occur in fracture-controlled veins, with values up to **0.05% molybdenum and 0.02% tungsten** reported.

Exploration has identified multi-element geochemical anomalies supported by geophysics, indicating a broader mineralized system. The showing is interpreted as a **porphyry-related gold and molybdenum system with skarn potential**.
